1 The Hawk-Dove game

The Hawk-Dove game was first formulated by John Maynard Smith and Georg Prince in 1973 [1]. The aim of the game is to gain a better understanding of conflicts in the animal kingdom. It consists of two players {Player One, Player Two} who have each two actions {Hawk, Dove}. The resulting payoff matrix can be seen in Table 1 where:

- V = fitness value of winning resources in fight
- D = fitness costs of injury
- T = fitness costs of wasting time

and we assume that $V, D, T \geq 0$.

Table 1: Hawk-Dove Payoff Matrix

| | | Player Two | |
|------------|------|------------|---------|
| | | Hawk | Dove |
| Player One | Hawk | $(V-D)/2$ | 0 |
| | Dove | V | $V/2-T$ |

In a mixed strategy game, we consider each player performing his action with a certain probability p or q , which results in the following payoff matrix displayed in Table 2.

Table 2: Hawk-Dove Probability Payoff Matrix

| | | Player Two | |
|------------|---------------|------------|---------------|
| | | P(Hawk)=q | P(Dove)=(1-q) |
| Player One | P(Hawk)=p | $(V-D)/2$ | 0 |
| | P(Dove)=(1-p) | V | $V/2-T$ |

With this table we are able to calculate the payoff of the actions Hawk and Dove for Player One:

Player One's expected payoff for the strategy Hawk(p) is:

$$q \times \frac{V-D}{2} + (1-q) \times V$$

Player One's expected payoff for the strategy Dove(1-p) is:

$$q \times 0 + (1-q) \times \left(\frac{V}{2} - T\right) = (1-q) \times \left(\frac{V}{2} - T\right)$$

The best response set is {Hawk} if:

$$q \times \frac{V-D}{2} + (1-q) \times V < (1-q) \times \left(\frac{V}{2} - T\right)$$

The best response set is {Dove} if:

$$q \times \frac{V-D}{2} + (1-q) \times V > (1-q) \times \left(\frac{V}{2} - T\right)$$

All the players mixed strategies are best responses if:

$$q \times \frac{V-D}{2} + (1-q) \times V = (1-q) \times \left(\frac{V}{2} - T\right)$$

As we are dealing with unknown variables, let's rewrite the equation for q :

$$q \times \frac{V-D}{2} + (1-q) \times V = (1-q) \times \left(\frac{V}{2} - T\right)$$

$$\frac{qV}{2} - \frac{qD}{2} + V - qV = \frac{V}{2} - T - \frac{qV}{2} + qT$$

$$-\frac{qD}{2} + V = \frac{V}{2} - T + qT$$

$$\frac{V}{2} + T = \frac{qD}{2} + qT$$

$$\frac{V}{2} + T = q\left(\frac{D}{2} + T\right)$$

$$V + 2T = q(D + 2T)$$

$$q = \frac{V + 2T}{D + 2T}$$

To find any pure or mixed strategy of this scenario, we have to look at different values for the variables V, D and T . In this, we must respect the following constraints:

$$0 \leq q \leq 1 \quad \text{and} \quad 0 \leq \frac{V + 2T}{D + 2T} \leq 1 \quad \text{and} \quad V, T, D \geq 0$$

1.1 $V+2T = 0$

This is only possible if $V = 0$ and $T = 0$ which gives $q = \frac{0}{D}$. We have to consider two cases: $D = 0$ and $D > 0$

1.1.1 $D=0$

Any pure or mixed strategy is a best response. This yields the mixed strategy NE $(p, q) \in \{(0 \leq p \leq 1), (0 \leq q \leq 1)\}$.

Table 3: $V=T=0, D>0$

| | | Player Two | |
|------------|------------------|-------------------|-------------------|
| | | P(Hawk)= q | P(Dove)= $(1-q)$ |
| Player One | P(Hawk)= p | $\textcircled{0}$ | $\textcircled{0}$ |
| | P(Dove)= $(1-p)$ | $\textcircled{0}$ | $\textcircled{0}$ |

1.1.2 $D > 0$

We have three pure strategy NE: {Dove,Hawk},{Hawk,Hawk} and {Hawk,Dove}. Solving for q gives $q = 0$ which does not yield a mixed strategy NE: $(p, q) = (0, 0)$.

Table 4: $V=T=0, D>0$

| | | Player Two | |
|------------|-------------------|--|--|
| | | P(Hawk)= q | P(Dove)=($1-q$) |
| Player One | P(Hawk)= p | $-D/2$ $-D/2$ | $\textcircled{0}$ $\textcircled{0}$ |
| | P(Dove)=($1-p$) | $\textcircled{0}$ $\textcircled{0}$ | $\textcircled{0}$ $\textcircled{0}$ |

1.2 $T=0$

With $T = 0$ we get the following payoff matrix:

Table 5: $T=0$

| | | Player Two | |
|------------|-------------------|------------------------|-------------------|
| | | P(Hawk)= q | P(Dove)=($1-q$) |
| Player One | P(Hawk)= p | $(V-D)/2$ $(V-D)/2$ | 0 V |
| | P(Dove)=($1-p$) | 0 V | $V/2$ $V/2$ |

We have the following scenarios: $V > D, V < D$ and $V = D$.

1.2.1 $V=D$

If we set $V = D$, we eliminate D from the payoff matrix:

Table 6: $T=0$

| | | Player Two | |
|------------|-------------------|--|--|
| | | P(Hawk)= q | P(Dove)=($1-q$) |
| Player One | P(Hawk)= p | $\textcircled{0}$ $\textcircled{0}$ | $\textcircled{0}$ \textcircled{V} |
| | P(Dove)=($1-p$) | $\textcircled{0}$ \textcircled{V} | $V/2$ $V/2$ |

With three pure strategy NE's: {Dove,Hawk},{Hawk,Hawk} and {Hawk,Dove}. To find mixed strategies, we need the expected payoff for both strategies:

Player One's expected payoff for the strategy Hawk(p) is:

$$q \times 0 + (1 - q) \times V = (1 - q) \times V$$

Player One's expected payoff for the strategy Dove($1-p$) is:

$$q \times 0 + (1 - q) \times V/2 = (1 - q) \times (V/2)$$

All the players mixed strategies are best responses if:

$$(1 - q) \times V = (1 - q) \times (V/2)$$

1.2.2 $V > D$

Not viable as

1.2.3 $V < D$

2 Which social dilemma?

Player A is confronted with one of three social dilemma's - the corresponding payoff matrix is shown in tables 7, 8 and 9. The player has to decide whether to cooperate (C) or to defect (D) without knowing which game he is actually facing. Each dilemma has the same probability 1/3 of being played. Opponent B knows the game.

Table 7: Prisonners dilemma

| | C | D |
|---|------|------|
| C | 2, 2 | 0, 5 |
| D | 5, 0 | 1, 1 |

Table 8: Stag-Hunt game

| | C | D |
|---|------|------|
| C | 5, 5 | 0, 2 |
| D | 0, 2 | 1, 1 |

Table 9: Snowdrift game

| | C | D |
|---|------|------|
| C | 2, 2 | 1, 5 |
| D | 5, 1 | 0, 0 |

with this information we can calculate the expected payoff for player A for every possible strategy of Player B - Table 10.

Table 10: Expected payoff for Player A

| | | Player B | | | | | | | |
|----------|---|----------|---------|---------|---------|---------|---------|---------|---------|
| | | (C,C,C) | (C,C,D) | (C,D,C) | (C,D,D) | (D,C,C) | (D,C,D) | (D,D,C) | (D,D,D) |
| Player A | C | 9/3 | 8/3 | 4/3 | 3/3 | 7/3 | 6/3 | 2/3 | 1/3 |
| | D | 12/3 | 7/3 | 11/3 | 6/3 | 8/3 | 3/3 | 7/3 | 2/3 |

From this table we can select the best response for Player A for each strategy of Player B - cells marked red in Table 11.

Table 11: Best responses for Player A

| | | Player B | | | | | | | |
|----------|---|----------|---------|---------|---------|---------|---------|---------|---------|
| | | (C,C,C) | (C,C,D) | (C,D,C) | (C,D,D) | (D,C,C) | (D,C,D) | (D,D,C) | (D,D,D) |
| Player A | C | 9/3 | 8/3 | 4/3 | 3/3 | 7/3 | 6/3 | 2/3 | 1/3 |
| | D | 12/3 | 7/3 | 11/3 | 6/3 | 8/3 | 3/3 | 7/3 | 2/3 |

Now we have to determine the best responses of Player B against Player A of the three different strategies - marked by green cells in Tables 12, 13 and 14.

Table 12: Prisonners dilemma

| | C | D |
|---|---|---|
| C | 2 | 5 |
| D | 0 | 1 |

Table 13: Stag-Hunt game

| | C | D |
|---|---|---|
| C | 5 | 2 |
| D | 0 | 1 |

Table 14: Snowdrift game

| | C | D |
|---|---|---|
| C | 2 | 5 |
| D | 1 | 0 |

The pure strategy Nash Equilibria can now be determined by matching these results. We find two Nash Equilibria at $\{C, (D, C, D)\}$ and $\{D, (D, D, C)\}$.

3 Sequential truel

This scenario considers three persons A,B and C, each of whom has a gun with a single bullet. If alive, each person may shoot at any surviving person. The order in which the scenario is played out is A, then B and then C. The probability that player i hits their target is denoted by p_i where $0 \leq p_i \leq 1$. Every player wishes to optimize her probability of survival. For this exercise we further assume that a player has to target another living player and is not allowed to miss a shoot consciously. The resulting diagram of this game is shown in Figure 1.

Figure 1: Sequential truel diagram

The Diagram shows all possible actions of all players with all possible outcomes. The lowest level leaf indicates which player is still alive and with which probability - $[0,0,1]$ indicates Player A and B being dead while Player C is alive with a probability of $p_a \times p_c$.
